## Presentation Highlights

In this paper, we analyze Silicon, GaN and SiC power transistors under the same circuit conditions.
We consider a 3 kW DC-DC power converter which operates with input of $400 \mathrm{~V} / 15 \mathrm{~A}$ and $800 \mathrm{~V} / 7.5 \mathrm{~A}$ at switching frequencies ranging from $1-200 \mathrm{kHz}$.

Using the power loss dashboard, we quickly identified $4000 \mathrm{Si}, \mathrm{SiC}$ and GaN power transistors that match our criteria from $\sim 25,000$ that are available in the market.

We compare the calculated power loss trends at different operating conditions of voltage, current, switching frequency while delivering the same amount of power.

We determine which devices offers the lowest power loss performance for their price. The study will help hardware engineers rapidly identify which devices are best for their applications.

## Circuit Conditions \& Power Loss Requirement

## Circuit Condition:

$\mathrm{Vds}=400 \mathrm{~V} \& 800 \mathrm{~V}$
$\mathrm{Ids}=15 \mathrm{~A} \& 7.5 \mathrm{~A}$
Fsw = 1, 10, 20, 100, 200 kHz
Duty cycle $=0.5$
Rg total $=10 \Omega$ (external + internal)
Tambient $=25 \mathrm{C}$
Gate drive $=10 \mathrm{~V}$

Total Power Loss (Requirement: $\leq 40 \mathrm{~W}$ )
Conduction $=I_{\mathrm{ds}}{ }^{2} \mathrm{R}_{\mathrm{ds}(\text { on })} * \mathrm{D}$
Switching $=\mathrm{F}_{\mathrm{sw}}{ }^{*} \mathrm{I}_{\mathrm{ds}} * \mathrm{~V}_{\mathrm{ds}}{ }^{*}\left(\mathrm{t}_{\mathrm{on}}+\mathrm{t}_{\text {off }}\right) / 2$
Diode Reverse Recovery $=\mathrm{Q}_{\mathrm{RR}} * \mathrm{~V}_{\mathrm{ds}}{ }^{*} \mathrm{~F}_{\mathrm{SW}}$

## Power Loss Dashboard

- We considered ~25,000 Mosfets from over 30 manufacturers in 750+ package types to create a power loss dashboard.
- Blue circle represents Silicon Mosfet, green square represents GaN FET and red triangle represents SiC FET.

## Results for Operation at $400 \mathrm{~V}, 15 \mathrm{~A}$, $\mathrm{D}=0.5$ from 1-200 kHz

- For a hypothetical 3 kW power converter, consider the first set of operating conditions $\mathrm{V}_{\mathrm{DS}}=$ $400 \mathrm{~V}, \mathrm{I}_{\mathrm{D}}=15 \mathrm{~A}, \mathrm{D}=0.5, \mathrm{R}_{\mathrm{G} \text { Total }}=10 \Omega, \mathrm{~T}_{\mathrm{AMB}}=25^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{GS}}=10 \mathrm{~V}$ at $\mathrm{F}_{\mathrm{SW}}$ of $1 \mathrm{kHz}, 10 \mathrm{kHz}, 20$ $\mathrm{kHz}, 100 \mathrm{kHz}$ and 200 kHz with requirement of device breakdown voltage rated between $600-900 \mathrm{~V}$ and maximum power loss of 40 W .
- For this power converter we consider power devices made of different materials - Si MOSFET, GaN HEMT and SiC FET. We then calculate the total power loss for each type of device using DiscoverEE's power loss dashboard and plot the total calculated power loss for the devices with respect to their maximum on-resistance, $\mathrm{R}_{\mathrm{DS}(\mathrm{ON}) \text { MAX }}$

## Operation at $400 \mathrm{~V}, 15 \mathrm{~A}$, 1 kHz

At 1 kHz operation, the lowest power losses among the available devices in the market today come from 650V, $9 \mathrm{~m} \Omega \mathrm{SiC}$ FET as it achieves the lowest on-resistance but at ${ }^{\sim} 3.4$ times the price of $600 \mathrm{~V}, 18 \mathrm{~m} \Omega$ Si device.

But we find that if the same power loss needs to be achieved Si device cost will only be slightly lower than that of SiC and GaN .

## Operation at 400 V, 15 A, 10 kHz

At 10 kHz , lowest power losses come from GaN device as it achieves the combination of low on-resistance, gate charge and reverse recovery loss. The price of GaN device is 2.4 times that of Silicon device and achieves $53 \%$ of power loss. Here SiC device offer are a good alternative as it costs 1.88 times the Silicon device and achieves $60 \%$ of the power loss.

## Operation at $400 \mathrm{~V}, 15 \mathrm{~A}$, 20 kHz

At 20 kHz operation, the lowest power loss come from GaN device followed by SiC device. The overall dynamics of device selection do not change much except that the GaN device is slightly more compelling as it achieves $45 \%$ power loss of the Si device vs. $60 \%$ from SiC device.

## Operation at 400 V, 15 A, 100 kHz

At 100 kHz operation, GaN device with the lowest power is 12.55 W and comes from $650 \mathrm{~V}, 90 \mathrm{~m} \Omega$ device with price of $\sim \$ 12$. Cascode GaN device with the lowest power is 18 W and comes from $650 \mathrm{~V}, 85 \mathrm{~m} \Omega$ device with price of $\$ 11.8$. For SiC , the lowest power loss of 25 W comes from a 650 y , $94 \mathrm{~m} \Omega$ device with price of $\$ 11.6$.

## Operation at $400 \mathrm{~V}, 15 \mathrm{~A}$, 200 kHz

At $200 \mathrm{kHz}, \mathrm{SiC}$ devices have high power loss and GaN devices appear to be only options for efficiently managing the thermals. We also observe that enhancement mode GaN devices are the best options for operating the power converter followed by the cascode configuration GaN devicer.

## Results for Operation at $800 \mathrm{~V}, 7.5 \mathrm{~A}, \mathrm{D}=0.5$ from 1-200 kHz

- For a hypothetical 3 kW power converter, consider the first set of operating conditions $\mathrm{V}_{\mathrm{DS}}=800 \mathrm{~V}, \mathrm{I}_{\mathrm{D}}=7.5 \mathrm{~A}, \mathrm{D}=0.5, \mathrm{R}_{\mathrm{G} \text { Total }}=10 \Omega, \mathrm{~T}_{\mathrm{AMB}}=25^{\circ} \mathrm{C}$ and $\mathrm{V}_{G S}=10 \mathrm{~V}$ at $\mathrm{F}_{\mathrm{sw}}$ of $1 \mathrm{kHz}, 10 \mathrm{kHz}, 20 \mathrm{kHz}, 100 \mathrm{kHz}$ and 200 kHz with requirement of device breakdown voltage between 1100-1700 V and maximum power loss of 40 W .
- For this power converter we consider power devices made of different materials - Si MOSFET, GaN HEMT and SiC FET. We then calculate the total power loss for each type of device using DiscoverEE's power loss dashboard and plot the total calculated power loss for the devices with respect to their maximum on-resistance, $\mathrm{R}_{\mathrm{DS}(\mathrm{ON}) \mathrm{MAX}}$

## Operation at 800 V, 7.5 A, 1 kHz

For high voltage operation at 800 V , even at low switching frequency of 1 kHz , Si MOSFET devices are no match to SiC both in terms of achieving power loss performance and cost. Of course, there are other types of devices such as IGBTs which are more suitable for such operation we have restricted this study to FET devices only in this paper.

## Operation at 800 V, 7.5 A, 10 kHz

At 10 kHz operation, the lowest power losses come from 1200 V SiC devices with $R_{\text {DS(ON)MAX }}$ in the range of $90-110 \mathrm{~m} \Omega$. No Si or GaN devices meet our criteria.

## Operation at 800 V, 7.5 A, 20 kHz

For SiC , the lowest power loss of 7.4 W is from $1200 \mathrm{~V}, 110 \mathrm{~m} \Omega$ device in TO-247 package. Distributor price for 1 unit is $\$ 10.7$.

Among cascode configuration SiC devices, there is $1200 \mathrm{~V}, 90 \mathrm{~m} \Omega$ device in TO-247 with very similar power loss of 8.3 W . Price of 1 unit is $\$ 14.39$.

## Operation at 800 V, 7.5 A, 100 kHz

For SiC , the lowest power loss of 18.8 W is from $1200 \mathrm{~V}, 294 \mathrm{~m} \Omega$ device in TO-247 package. Distributor price for 1 unit is $\$ 10.3$.

Among SiC devices cascode configuration, there is $1200 \mathrm{~V}, 180 \mathrm{~m} \Omega$ device in TO-247 with very similar power loss of 21.8 W . Price of 1 unit is $\$ 8.3$. $\stackrel{\Delta}{\Delta}$
$\rightarrow$ SiCcascode: $1200 \mathrm{~V}, 180 \mathrm{~m} \Omega, 38.5 \mathrm{~W}, \$ 8.3$
SiC: $1200 \mathrm{~V}, 468 \mathrm{~m} \Omega, 28.7 \mathrm{~W}, \$ 8.3$

0.50

Drain to Source On-Resistance [Ohm]

## Operation at 800 V, 7.5 A, 200 kHz

For 200 kHz operation, only a handful of 1200 V devices with $\mathrm{R}_{\mathrm{DS}(\mathrm{ON}) \mathrm{max}}$ in the range of $180-468 \mathrm{~m} \Omega$ meet power loss criteria and lowest power loss achieved is 29.4 W . The lowest power loss of SiC devices with cascode configuration is $34 \%$ higher which can be reduced if the devices were to be optimized for this operating condition.

## Summary

| $400 \mathrm{~V}, 15 \mathrm{~A}$ | 1 kHz | 10 kHz | 20 kHz | 100 kHz | 200 kHz |

DiscoverEE

## Conclusion

Our study shows that the choice of device material for minimizing power loss depends on the operating conditions (V, I, f, D, Vgs, Rg etc.) as well as characteristics of the material and device.

For operation at $400 \mathrm{~V} / 15$ A with devices rated at $600-900 \mathrm{~V}$ :
1 kHz or lower: Si devices offer a very good performance for their price.
$10-20 \mathrm{kHz}$ : GaN offers lowest power loss but SiC devices offer a good value at comparable losses $100-200 \mathrm{kHz}$ : GaN devices achieve the lowest power loss by a wide margin over SiC and Si devices.

For operation at $800 \mathrm{~V} / 7.5 \mathrm{~A}$ with devices rated at $1100-1700 \mathrm{~V}, \mathrm{SiC}$ is the clear winner for achieving the lowest power loss for low as well as high frequency operation.

Power losses increase substantially with switching frequency and our study shows that:
At 20 kHz or lower, it is beneficial to operate the converter at higher voltage and use SiC devices. At 100 kHz or higher, it is beneficial to operate the converter at lower voltage with GaN devices.
